Abstract Let \( G(n) \) denote the number of partitions of \( n \) into distinct parts which are of the form \( 2m, 3m, 5m, 6m-3, 8m-3, 9m-3 \) or \( 11m-3 \) with parts of the form \( 2m, 3m, 6m-3, \) or \( 11m-3 \) being even in number minus the number of them with parts of the form \( 2m, 3m, 6m-3, \) or \( 11m-3 \) being odd in number. In this paper, we prove that \( G(n) \) assumes all integral values and does so infinitely often.

Keywords: partition functions, Gaussian integers, Jacobi’s triple product identity

1. Introduction

Let \( S(n) \) denote the number of partitions of \( n \) into distinct parts with even rank minus the number with odd rank (see [2]). Andrew, Dyson and Hickerson [3] used the arithmetic of \( \mathbb{Q}(\sqrt{6}) \) to show that \( S(n) \) takes on every integral value infinitely often. This is the first time the interaction between the theory of partitions and algebraic number theory was exhibited. It was remarked in [3] that they know of no other partition function in the literature which assumes all integral values as \( S(n) \) does.

Let \( H(n) \) denote the number of partitions of \( n \) into parts which are repeated exactly 1, 3, 4, 6, 7, 9, or 10 times with the parts repeated exactly 1, 4, 6, or 9 times odd in number minus the number of them with parts repeated exactly 1, 4, 6, or 9 times odd in number. In [5], using the arithmetic of Gaussian integers \( \mathbb{Z}[\sqrt{i}] \), it was shown that \( H(n) \) assumes all integral values and does so infinitely often.

Let \( G(n) \) denote the number of partitions of \( n \) into distinct parts which are of the form \( 2m, 3m, 5m, 6m-3, 8m-3, 9m-3, \) or \( 11m-3 \) with parts of the form \( 2m, 3m, 6m-3, \) or \( 11m-3 \) being odd in number minus the number of them with parts of the form \( 2m, 3m, 6m-3, \) or \( 11m-3 \) being odd in number. For example, \( G(7) \) is zero because \((2(2)) + (3(1)) + (6(1)-3) \) have even number of parts of the form \( 2m, 3m, 6m-3, \) or \( 11m-3 \) (here m-values are shown in bold). In this paper, we show that \( G(n) \) assumes all integral values and does so infinitely often.

2. Main Results

A For (positive) integer \( n \), consider the equation

\[
  u^2 + v^2 = 24n + 2 \tag{2.1}
\]

We call a solution \((u, v)\) of (2.1) admissible if \( u \equiv 1 \) (mod 6) and \( v \equiv 1 \) (mod 6). For a (positive) integer \( n = 2 \) (mod 24), let \( J(n) \) be the excess of the number of admissible solutions of \( u^2 + v^2 = n \) with \( v \equiv 1 \) (mod 12) over the number of them with \( v \) not congruent to 1 modulo 12.

In subsequent sections, we shall be proving the following:

**Theorem 1.** For \( n \geq 0 \), \( G(n) = J(24n + 2) \).

**Theorem 2.** \( G(n) \) takes on every integer value infinitely often.

3. Proof of Theorem 1

First we note that the generating function of \( G(n) \) is

\[
  \sum_{n \geq 0} G(n)q^n = \prod_{n \geq 1} \left( \frac{1 - q^{2n} - q^{3n} + q^{5n} - q^{6n-3}}{1 + q^{8n-3} + q^{9n-3} - q^{11n-3}} \right)
\]

**Lemma 1.** For \( |q| < 1 \),

\[
  \prod_{n \geq 1} \left( \frac{1 - q^{2n} - q^{3n} + q^{5n} - q^{6n-3}}{1 + q^{8n-3} + q^{9n-3} - q^{11n-3}} \right) = \sum_{n, m \in \mathbb{Z}} (-1)^m q^{3(n^2 + m^2)} \cdot \frac{1}{2(n+m)}
\]

**Proof.** Using Jacobi’s triple product identities (see [1], p. 21) we get
\[
\sum_{n,m \in \mathbb{Z}} (-1)^m q^2 \left( n^2 + m^2 \right) + \frac{1}{2}(n+m) \\
= \left( \sum_{n \in \mathbb{Z}} \frac{3}{2n^2 + 1 + \frac{n}{2}} \right) \left( \sum_{m \in \mathbb{Z}} (-1)^m q^2 \frac{3}{2m^2 + 1 + \frac{m}{2}} \right) \\
= \prod_{n \geq 1} \left( 1 - q^{3n} \right) \left( 1 - q^{3n-1} \right) \\
\times \prod_{n \geq 1} \left( 1 - q^{3n-2} \right) \\
= \prod_{n \geq 1} \left( 1 - q^{3n} \right)^2 \left( 1 + q^{6n-2} \right) \left( 1 + q^{6n-4} \right) \\
= \prod_{n \geq 1} \left( 1 - q^{3n} \right) \left( 1 - q^{2n} \right) \left( 1 - q^{6n-3} \right) \\
= \prod_{n \geq 1} \left( 1 - q^{2n} - q^{3n} + q^{5n} - q^{6n-3} - q^{11n-3} \right) \\
= \sum_{n \geq 0} G(n)q^n.
\]

This proves the Lemma.

Using this Lemma, it follows that:
\[
\sum_{n \geq 0} G(n)q^{24n+2} \\
= q^2 \prod_{n \geq 1} \left( 1 - q^{48n} - q^{72n} + q^{120n} - q^{144n-72} \right) \\
= q^2 \sum_{n,m \in \mathbb{Z}} (-1)^m q \left( n^2 + m^2 \right) + 12(n+m) \\
= \sum_{n,m \in \mathbb{Z}} (-1)^m q \left( 6n+1 \right)^2 + (6m+1)^2 \\
= \sum_{n \geq 0} J(24n+2)q^{24n+2}.
\]

This proves Theorem 1.

4. Arithmetic of \( J(n) \)

In this section we study \( J(n) \) using Gaussian integers \( \mathbb{Z}[i] \), where \( i = \sqrt{-1} \). For \( \alpha = u + iv \in \mathbb{Z}[i] \), let \( N(u+iv) = u^2 + v^2 \). We define \( c_4(\alpha) \) in terms of \( u \) (mod 4) and \( v \) (mod 4) by

\[\begin{array}{c|cccc}
\nu(\text{mod} \ 4) & 0 & 1 & 2 & 4 \\
\hline 
u(\text{mod} \ 4) & 0 & 0 & i & 0 \\
& 1 & 1 & 0 & -1 \\
& 2 & 0 & -i & 0 \\
& 4 & -1 & 0 & 1 \\
\end{array}\]

Let \( c_4(\alpha) \) be defined in terms of \( u \) (mod 3) and \( v \) (mod 3) by the following table, where \( \omega = (1+i)/\sqrt{2} \):
An arithmetical function \( f(n) \) is called \textit{lacunary} if it is almost always 0 (see [4]). In [3] it is shown that \( S(n) \) is lacunary. In [5] it is shown that \( H(n) \) is lacunary. So it is natural to ask whether \( G(n) \) is so. We make the following conjecture:

**Conjecture.** \( G(n) \) is lacunary.
