20  
21 9 The variability of carboxylate linkers in eight new [Zn(II)(cyclam)]<sup>2+</sup> compounds (**1-8**) leading to  
22 10 rich structural diversity and dimensionality is presented in this paper. The [Zn(II)(cyclam)]<sup>2+</sup>  
23 11 featuring *ortho*-substituted benzoate ligands were synthesized and characterized by various tools.  
24 12 Compounds **1** and **2** exhibit one-dimensional polymeric structures, wherein aqua ligands bridging  
25 13 cationic and anionic units leading to [Zn<sub>2</sub>(μ-H<sub>2</sub>O)<sub>2</sub>(cyclam)(L)<sub>4</sub>] (where L = *o*-methyl benzoate  
26 14 in **1**, L = *o*-methoxy benzoate in **2**, cyclam = 1,4,8,11-tetraazacyclotradecane). Hydroxy and nitro  
27 15 substitution at *ortho* positions have led to zero-dimensionality in compounds **3** and **4**,  
28 16 [Zn(C<sub>10</sub>H<sub>24</sub>N<sub>4</sub>)(L)<sub>2</sub>] (L = *o*-hydroxybenzoate in **3**, L = *o*-nitrobenzoate in **4**). Interestingly, using  
29 17 benzoate, *o*-chlorobenzoate, *o*-(methylthio)benzoate, and *o*-aminobenzoate substituents resulted in  
30 18 significant variation in the crystal packing, leading to discrete ionic compounds **5-8**. An  
31 19 investigation into isostructurality revealed a higher cell similarity and a lower isostructurality  
32 20 index for the **1,2** pair; in contrast, the pair of **3,4** and a group of compounds **5-7** were identified as  
33 21 non-isostructural. To get a deeper insight into the noncovalent interactions governing the  
34 22 supramolecular self-assemblies, we have performed Hirshfeld surface analysis for all compounds,  
35 23 and the results are presented.

## 1. Introduction

Cyclam (1,4,8,11-tetraazacyclotetradecane) is a macrocyclic N-donor ligand that has been generously employed in the synthesis of metal complexes due to its ability to render inertness and chemical stability to the metal complex in its parent form or when is suitably *N*-functionalized<sup>1-2</sup>. The metal chelates prepared using cyclam find their application in various fields, including medicine, catalysis, and molecular sensors<sup>3-6</sup>. Besides offering high binding affinity to small transition metal ions, cyclam also adopts various configurations due to its flexibility when interacting with the metal ions and the other supporting ligands. In 1965, Bosnich *et al.* described five configurations adopted by the cyclam ligand under the influence of the transition metal ion<sup>7</sup>. The orientation of the N-H group in coordinated cyclam defines the type of isomer, which can be classified as *trans*-I- IV, and the unusual folded *cis*-V configuration in the metal compounds. Among these, the *trans*-III configuration is the most stable and predominates in the cyclam-based compounds compared to the other forms<sup>8-11</sup>. The nature of the counter anion greatly influences the relative population of the different configurations present in the solution state<sup>12,13</sup>. In 2003, Sadler *et al.*, via the NMR technique, highlighted the influence of the counterion on the type of isomer present in the solution state. In addition, the solid-state examination of the crystal structure provided valuable information on the configuration adopted by the cyclam ligand.

The structural insights into the chelating metal complexes, such as those involving cyclam ligands, play a crucial role in understanding their properties and potential applications, such as inhibitory effect on the replication of human immunodeficiency virus (HIV). In the case of cyclam-based compounds, the interaction with the co-receptor CXCR4 is indeed intriguing. The carboxylate group of the aspartate residue in CXCR4 likely forms non-covalent interactions with the cyclam ligand, contributing to its binding affinity<sup>14,15</sup>. Given these, developing new anti-HIV drugs of cyclam compounds requires a better understanding of the conformations and crystal packing forces. Due to the tendency of the cyclam ligand to adopt different configurations, the coordinated cyclam may be recognized by the receptor differently. This has invoked an increasing activity in studying the interaction of the carboxylate moieties with metal cyclam core. In 2005, Jo *et al.*, studied the molecular interaction of four compounds  $[\text{Zn}(\text{L})(\text{tp})]\cdot\text{H}_2\text{O}$ ,  $[\text{Zn}(\text{L})(\text{H}_2\text{bta})]\cdot 2\text{H}_2\text{O}$ ,  $[\text{Zn}_2(\text{L})_2(\text{ox})]_2\text{ClO}_4\cdot 2\text{DMF}$  and  $[\text{Zn}(\text{L})(\text{H}_2\text{bta})]\cdot 2\text{H}_2\text{O}$  where L = cyclam, tp = 1,4-benzenedicarboxylate, H<sub>2</sub>bta = 1,2,4,5-benzenetetracarboxylate, ox = oxalate and H<sub>2</sub>btc = 1,3,5-

1  
2  
3  
4 59 benzenetricarboxylate ions. The structural analysis of the above compounds reveals strong  
5  
6 60 coordination of the carboxylate anions with the  $[\text{Zn}(\text{cyclam})]^{2+}$  core. The presence of the oxalate  
7  
8 61 ligand, which adopts a bridging coordination mode, in compound  $[\text{Zn}_2(\text{L})_2(\text{ox})]_2\text{ClO}_4 \cdot 2\text{DMF}$ ,  
9  
10 62 thereby forcing the cyclam ligands on each zinc ion to adopt the *cis*-V configuration. Meanwhile,  
11  
12 63 the cyclam in the other mononuclear compounds adopts the most stable *trans*-III configuration  
13  
14 64 around the zinc ion <sup>16</sup>. In 2006, Kim *et al* studied the molecular interaction of two metal cyclam  
15  
16 65 compounds, namely  $[\text{Zn}(\text{L})(\text{Maleate})] \cdot \text{H}_2\text{O}$ ,  $[\text{Zn}(\text{L})(\text{H}_2\text{O})_2](\text{fumarate}) \cdot 4\text{H}_2\text{O}$  where L = cyclam.  
17  
18 66 Incorporating a dibasic maleate ligand formed a 1D coordination polymer wherein the maleate  
19  
20 67 ligand bridges the two  $[\text{Zn}(\text{cyclam})]^{2+}$  cores and forms a coordinatively saturated compound. On  
21  
22 68 the contrary, the fumarate ligand, having a similar basicity as that of maleate, does not coordinate  
23  
24 69 with the central metal ion. This selective, strong interaction with zinc was assumed to be because  
25  
26 70 of the conformation of the ligand, which enables the formation of hydrogen bonds as compared to  
27  
28 71 the fumarate ligand, where the carboxylate groups are trans to each other <sup>17</sup>. As the example above  
29  
30 72 shows, the crystal packing arrangements can be altered by changing the chemical composition,  
31  
32 73 which can also be achieved by modifying the substituents. Their type and placement in a multi-  
33  
34 74 component system can gradually influence the crystal packing arrangement, potentially leading to  
35  
36 75 the formation of isostructural compounds or disruption in isostructurality. For related compounds  
37  
38 76 to exhibit isostructurality, they must share a similar chemical composition and conformation of the  
39  
40 77 compounds, with the highly analogous supramolecular arrangement in the crystal lattice having  
41  
42 78 the same space group. <sup>18-20</sup> Bombicz and co-workers highlighted various methods to recognize  
43  
44 79 isostructurality in related compounds. These methods include numerical descriptors such as cell  
45  
46 80 similarity ( $\pi$ ), isostructurality (*I*<sub>s</sub>), and molecular isometricity indices. Statistical approaches help  
47  
48 81 investigate the extent of isostructurality exhibited by related compounds with the same space group  
49  
50 82 and *Z* <sup>18</sup>. Our work intends to expand the literature on zinc-cyclam-based compounds with varying  
51  
52 83 *ortho* substituents and further extend our understanding of the mode of interaction of the  
53  
54 84 carboxylate anions with the zinc-cyclam unit and their influence on the supramolecular  
55  
56 85 arrangement.

4 89 **2. Results and discussion**

5  
6  
7 90 **2. 1. Synthetic aspects, spectroscopic and structural characterization of 1-8**

8  
9  
10 91 The crystallographic data and the refinement parameters of compounds **1-4** are given in **Table 1**,  
11 92 and **5-8** are given in **Table S1**. Compounds **1-8** were obtained *via* slow evaporation method at  
12  
13 93 room temperature, wherein aqueous Zn(OAc)<sub>2</sub>·2H<sub>2</sub>O solution was initially mixed with the  
14  
15 94 corresponding carboxylic acid (L1-L8) separately and stirred at 80°C until a clear solution was  
16  
17 95 obtained. The resulting solution was then reacted with cyclam ligand for 1 hr. Upon standing at  
18  
19 96 room temperature, this reaction mixture afforded suitable single crystals of compounds **1-8**, which  
20  
21 97 were then washed using cold distilled water and used for further analysis. A general scheme  
22  
23 98 showing the synthetic route for **1-8** is shown in **Scheme 1**. The IR spectroscopic analysis revealed  
24  
25 99 that compounds exhibit sharp bands in the region of ~1700 and 1400 cm<sup>-1</sup>, which are attributed to  
26 100 the characteristic absorption band for asymmetric and symmetric stretching vibration of the  
27  
28 101 carboxylate (COO<sup>-</sup>) anion, thus suggesting the incorporation of the carboxylate moieties in the  
29  
30 102 respective compounds as depicted in **Figure S1**. The broad absorption band centered at 3369 (**1**),  
31  
32 103 3398 (**2**), 3310(**3**), 3340(**4**), 3412(**5**), and 3378 (**6**) cm<sup>-1</sup> is attributed to the O-H stretching vibration  
33  
34 104 of the aqua molecules. Medium to weak stretching vibration bands due to C-H and N-H vibration  
35 105 in the organic moieties were seen in the 3100 -2800 cm<sup>-1</sup> range in all eight compounds.

106

107 **Scheme 1.** General preparative scheme for compounds **1-8**

108 **2.2. Thermal investigation of compounds 1 and 5**

109 The thermal decomposition pattern of compound **1** was compared with the decomposition pattern  
 110 of **5**, consisting of the parent benzoate ligand. The thermal profiles of **1** are depicted in **Figure 1**.  
 111 The first mass loss in both compounds is due to the removal of the coordinated water molecules.  
 112 In compound **1**, the first mass loss occurs between 90-150°C, accounting for 4 % (*calcd.* 3.97 %)   
 113 mass loss attributed to the loss of the bridging type of aqua molecules with two endotherms in the  
 114 DTA pattern centered at 118 and 145 °C. In contrast, in compound **5** (**Figure S2**), the aqua  
 115 molecules are lost at a much lower temperature range, between 80 °C to 125 °C, due to the  
 116 monodentate coordination mode of the water molecules. This process is evident from an  
 117 endotherm at 87 °C in the DTA pattern. The following mass loss of 22.72 % (*calcd.* 22.07 % in **1**)  
 118 and 36.92 % (*calcd.* 37 % in **5**) is attributed to the decomposition of the cyclam ligand in the range  
 119 of 250 -350°C. Upon dehydration and decomposition of the cyclic amine, further heating in **1** till  
 120 700 °C results in a mass loss of 56.17 % in **1** (*calcd.* 56.05 %) and 39.28 % in **5** (*calcd.* 41.6 %) is  
 121 observed due to the decomposition of the carboxylate ligands, (*o*-methoxybenzoate and benzoate)  
 122 in respective compounds. The final residue of 17.22 % was observed in the case of compound **1**

1  
2  
3  
4 123 and is in good agreement with the calculated 17.9 % for ZnO. Similar results were obtained for  
5  
6 124 compound 5.

125  
126 **Figure 1.** The thermal decomposition plot of compound 1 was recorded in the nitrogen atmosphere  
127 between room temperature to 760 °C at a heating rate of 10 °C min<sup>-1</sup>.

### 128 2.3. Structural description of crystal structure, isostructurality descriptors, and Hirshfeld 129 analysis 1-8

130 The structural analysis of the eight compounds reveals that the macrocyclic ligand consistently  
131 adopts the *Trans*-III configuration irrespective of the carboxylate anion used, which is recognized  
132 as the most stable configuration adopted by the cyclam ligand. The observed structural variation  
133 is thus primarily attributed to the interactions between the carboxylate anions with varying *ortho*  
134 substituents and the zinc cyclam core. Moreover, the compounds were classified based on the  
135 similarities in their unit cell parameters and examined for isostructurality. For a compound to  
136 demonstrate isostructurality, it must have unit cell parameters similar to those of related  
137 compounds. The zinc series, consisting of eight compounds, was divided into three groups to  
138 elucidate the structural relationship and variation among them. Compounds 1 and 2 were placed  
139 in *Group I* as they crystallized in the monoclinic system with the *C2/m* space group. 3 and 4 were

1  
2  
3  
4 140 assigned to *Group II* as they crystallized in the orthorhombic system with  $Pbc$  space group.  
5  
6 141 *Group III* included compounds **5**, **6**, and **7** crystallized in the monoclinic  $P2_1/n$  space group.  
7  
8 142 Compound **8** did not fit into these groups, as it crystallized in the monoclinic crystal system with  
9  
10 143 the  $C2/c$  space group.

11  
12 144 The crystal structure of compounds **1** and **2** (*Group I*) exhibits a one-dimensional *zig-zag* chain  
13  
14 145 structure due to bridging aqua molecules located on a two-fold crystallographic axis that binds to  
15  
16 146 the  $[Zn(cyclam)]^{2+}$  cationic and the anionic units  $[Zn(L)_4]^{2-}$ . The crystal structure of compound **1**,  
17  
18 147 shown in **Figure 2a**, comprises two crystallographically independent  $Zn^{2+}$  ions occupying the  
19  
20 148 special positions (Zn1 and Zn2) and adopts distorted octahedral geometry. The  $Zn \cdots Zn$  distance  
21  
22 149 across the chain is 4.318 Å. The Zn1 ion is coordinated with the cyclam ligand *via* four nitrogen  
23  
24 150 atoms (N1, N1i, N1ii, N1iii) on the equatorial plane. The axial positions are occupied by the  
25  
26 151 oxygen atom (O1W and O1W<sup>iii</sup>) from the bridging aqua molecules, thus forming  $\{ZnN_4O_2\}$   
27  
28 152 coordination environment. On the other hand, the  $Zn^{2+}$  ion is coordinated to six oxygen atoms  
29  
30 153 forming the  $\{ZnO_6\}$  core, wherein the four oxygen atoms are contributed by the carboxylate group  
31  
32 154 of *o*-methyl benzoate ligands (L) as depicted in **Figure 2b**. The O-donor ligand adopts a  
33  
34 155 monodentate coordination mode, and axial oxygen atoms are contributed by the bridging aqua  
35  
36 156 molecules (O1W and O1W<sup>iii</sup>). A similar crystal structural arrangement is identified in compound  
37  
38 157 **2**, shown in the ORTEP diagram **Figure S3**.

159 **Figure 2** a) The ORTEP diagram of compound **1** shows a portion of the chain with an atom  
60 160 labeling scheme. Thermal ellipsoids are drawn at 30 % probability except for the hydrogen atoms.

1  
2  
3  
4 161 The hydrogen atoms on the cyclam and the carboxylate ligand have been omitted for clarity.  
5  
6 162 Symmetry codes *i) -x, 1-y, 1-z, ii) x, 1-y, z, iii) -x, y, 1-z, iv) 1-x, 1-y, 1-z and v) 1-x, y, 1-z* b)  
7  
8 163 Carboxylate adopting monodentate coordination mode around Zn2 ion in compound **1**.  
9

10 164  
11 165 The Zn1 and Zn2 atoms in both compounds show distorted octahedrons due to the elongation of  
12  
13 166 the axial bonds. For instance, the O1W atom coordinated to the [Zn(cyclam)]<sup>2+</sup> unit shows a longer  
14  
15 167 Zn1-O1W bond distance of 2.448(17) and 2.463(4) Å as compared to the O1W atom coordinated  
16  
17 168 to the [Zn(L)<sub>4</sub>]<sup>2+</sup> unit with the bond distance of 2.255(17) and 2.222(3) Å in **1** and **2** respectively.  
18  
19 169 Even though the acid counterpart is different, the Zn1-O1W-Zn2 bond angles in both compounds  
20  
21 170 are very close, at **1** 133.23 (19) and **2** 132.49 (17)°. The selected bond distances and angles for **1**  
22  
23 171 and **2** are summarized in **Table 2**. Similar distortion is seen in related aqua-bridged compounds  
24  
25 172 reported in the literature<sup>21-25</sup>.

26  
27 173 A better view of the non-covalent inter-molecular hydrogen bonding interactions such as N-H···O,  
28  
29 174 O-H···O, and C-H···O, along with  $\pi$ - $\pi$  stacking interactions between aromatic benzene rings of  
30  
31 175 the acid component aid in stabilizing the crystal lattice are achieved with structural analysis. Each  
32  
33 176 cationic unit interacts with an anionic unit with the help of N1-H1<sub>(cyclam)</sub>···O1<sub>(carboxylate)</sub> with a  
34  
35 177 donor-acceptor distance of 3.012 Å. Further, the hydrogen atoms of the bridging aqua ligand are  
36  
37 178 also involved in hydrogen bonding with the uncoordinated oxygen atoms of the carboxylate ligand  
38  
39 179 O1W-H1W<sub>(aqua)</sub>···O2<sub>(carboxylate)</sub> with a donor-acceptor distance of 2.62 Å, thus playing significant  
40  
41 180 in the stabilization of the structure. The formation of a one-dimensional (1-D) coordination  
42  
43 181 polymer with intermolecular hydrogen bonds is shown in **Figure 3a**. Moreover, the 1-D chain is  
44  
45 182 also supported through C-H···O and  $\pi$ - $\pi$  interactions. Each adjacent aromatic ring of the  
46  
47 183 carboxylate interacts with weak  $\pi$ - $\pi$  stacking interaction (centroid distance of 4.82 Å), as shown  
48  
49 184 in **Figure 3b**. These weaker interactions extend the 1-D chain into a 3-D supramolecular network  
50

202  
 203 The extent of isostructurality in molecular pairs can be described based on geometrical descriptors  
 204 such as cell similarity ( $\pi$ ), isostructurality ( $I_s$ ), and molecular isometricity indices. The  
 205 isostructurality index offers a strict criterion for structural similarity, accounting for the

1  
2  
3  
4 206 geometrical and positional differences caused by rotation and translation<sup>18,26</sup>. The cell similarity  
5  
6 207 index obtained for the molecular pair **1** and **2** was 0.037, close to zero, suggesting similar unit cell  
7  
8 208 parameters. However, the lower isostructurality index of 37% indicates a considerable difference  
9  
10 209 in the close packing of the two compounds. Furthermore, the mercury software was used to overlay  
11  
12 210 the asymmetric unit of the related molecules, as depicted in **Figure 4a**, to obtain the rmsD and  
13  
14 211 max D values. A higher deviation of the max D (3.7119 Å) from zero can be attributed to varying  
15  
16 212 orientations of the substituents, which assume almost opposite directions. Analysis of the  
17  
18 213 geometrical parameters of the carboxylate anion highlights how substituents disrupt the  
19  
20 214 isostructurality in compounds **1** and **2**. Due to the ortho effect, the carboxylate group exhibits a  
21  
22 215 slight bend around the ring in both compounds. The dihedral angles between the ring carrying the  
23  
24 216 substituent and the plane defined by (O1-C4-O2) are 64.93 in (**1**), as shown in **Figure 4b**, and  
25  
26 217 73.82° in compound **2**. Additionally, the torsion angle (C5-C6-C7-C8-C9-C10) in compound **1** is  
27  
28 218 115.73° and -106.81 in compound **2**. These variations suggest that substituents might greatly  
29  
30 219 induce conformational changes, leading to a loss of isostructurality between the related  
31  
32 220 compounds.

221  
222 **Figure 4 a).** Overlay diagram of the asymmetric units of **1** (yellow) and **2** (green) compounds with  
223 rmsD = 1.9347 and max = 3.711 Å. **b).** View along the carboxylate anion highlighting the  
224 orientation of the substituents (left) and dihedral angle between the mean plane through benzene  
225 ring (C5-C6-C7-C8-C9-C10) and (O1-C4-O2) (right)

1  
 2  
 3  
 4 227 To further investigate the supramolecular non-covalent interactions in compounds **1** and **2**,  
 5  
 6 228 Hirshfeld surface (HS) analysis was performed. HS effectively quantifies the intermolecular  
 7  
 8 229 interaction in the crystals. The  $d_{\text{norm}}$  surfaces with short contacts, where the distance between the  
 9  
 10 230 atoms is shorter than the sum of their van der Waals radii are indicated in red. The  $d_{\text{norm}}$  mapping  
 11  
 12 231 reveals strong hydrogen bonds such as N-H $\cdots$ O contacts between the N atoms of the cyclam in  
 13  
 14 232 the cationic unit and oxygen of the neighboring carboxylate ligand as a bright red area in the  
 15  
 16 233 surface as shown in **Figure 5a, e** for compounds **1** and **2** respectively. In both compounds, the  
 17  
 18 234 predominant interactions are of the H $\cdots$ H type, accounting for up to 67 % in compound **1**, which  
 19  
 20 235 consists of methyl benzoate anion as the anion. However, with the introduction of methoxy  
 21  
 22 236 benzoate in the structure of compound **2**, the H $\cdots$ H type interaction reduces by 9.4 %. Other  
 23  
 24 237 significant interactions include C $\cdots$ H/ H $\cdots$ C and O $\cdots$ H/ H $\cdots$ O type seen in both the compounds.  
 25  
 26 238 Given the change as mentioned earlier in the anion source, an increment of 10% is observed in the  
 27  
 28 239 contribution from the O $\cdots$ H/ H $\cdots$ O type of interaction in compound **2**, with compound **1**  
 29  
 30 240 accounting for 12.2%. The intermolecular interactions arising due to C $\cdots$ H/ H $\cdots$ C are nearly the  
 31  
 32 241 same in both compounds, contributing 19.4% and 18.9 % in **1** and **2**, respectively. The 2D  
 33  
 34 242 fingerprint plots are illustrated in **Figure 5b-d** and **5f-h** for compounds **1** and **2**, respectively.

244  
 245 **Figure 5** Intermolecular N-H $\cdots$ O interactions in **1** (a) and **2** (e). 2D Fingerprint showing full,  
 246 O $\cdots$ H/H $\cdots$ O and C $\cdots$ H/H $\cdots$ C type interactions with the percentage of contribution to the total  
 247 Hirshfeld surface area in compound **1** (b-d) and **2**(f-h).

1  
2  
3  
4 248 Interestingly, the 1-D chain structure in compound **2** was retained by substituting the methyl group  
5  
6 249 with the methoxy group. This observation prompted further investigation with other simple  
7  
8 250 substituents. Compound **3** was synthesized using the *o*-hydroxy benzoic acid. Structural analysis  
9  
10 251 revealed that **3** formed a discrete zero-dimensional compound rather than a one-dimensional  
11  
12 252 polymeric structure. Compound **3** crystallized in an orthorhombic crystal system with *Pbc*a space  
13  
14 253 group. The crystal structures consist of a unique zinc ion on the inversion center, due to which half  
15  
16 254 of the molecule is symmetry generated. The zinc ion adopts the octahedral geometry with four  
17  
18 255 equatorial positions of the octahedron occupied by the nitrogen atoms of the cyclam ligand (N1,  
19  
20 256 N1<sup>i</sup>, N2, N2<sup>i</sup>). The axial positions are taken by the oxygen atoms (O1 and O1<sup>i</sup>) contributed by the  
21  
22 257 corresponding carboxylate anion, coordinating with the central metal ion *via* monodentate  
23  
24 258 coordination mode shown in **Figure 6a**. Compound **3** is isomorphous to **4**, synthesized using *o*-  
25  
26 259 nitrobenzoic acid. **4** exhibited similar unit cell parameters and coordination environment, as seen  
27  
28 260 in **3**, depicted in **Figure 6b**. The distortion in the octahedron of **3** is evident from the slightly  
29  
30 261 longer Zn-O (2.1874 (12) Å) bonds as compared to the Zn-N (2.0924 (14) Å) bond lengths. Similar  
31  
32 262 observations are made for **4**. The selected bond lengths and angles of compound **3** and **4** are  
33  
34 263 summarized in **Table S2**. The crystal packing is stabilized by non-covalent N-H $\cdots$ O, O-H $\cdots$ O,  
35  
36 264 and C-H $\cdots$ O hydrogen bonds. The intermolecular bonding situation in **3**, wherein C9 (donor atom)  
37  
38 265 of the cyclam ligand interacts with the adjacent molecules through the uncoordinated oxygen atom  
39  
40 266 O2 (acceptor atom) with a D $\cdots$ A distance of 3.325 Å, as a result of which a supramolecular  
41  
42 267 network is formed. A view of the supramolecular assembly of **3** is shown in **Figure 7b**. The  
43  
44 268 hydrogen bonding parameters are summarized in **Table 3**.

24 **Figure 6.** The thermal ellipsoid plot of compounds **3** (a) and **4** (b) with atom labeling scheme.

50 273 **Figure 7** a) The C-H...O intermolecular hydrogen bonding situation in **3** b) A view of 2D  
51  
52 274 supramolecular network in **3**.

53 275  
54  
55 276 Compounds **3** and **4** showed isomorphism, reflected in the cell similarity index ( $\pi$ ) with a value of  
56  
57 277 0.0192, which is very close to zero, suggesting a higher resemblance in the unit cell parameters.  
58  
59 278 However, these two compounds do not exhibit isostructurality. The asymmetric units were further

overlaid to obtain the rmsD and max D values, as [Figure S4](#) depicts. A higher deviation of the max D value of 3.5487 indicates a variation in the crystal structure packing of the two compounds influenced by the different substituents. Unlike the methyl or methoxy substituent, the hydroxy substituent is involved in intramolecular hydrogen bonding with the carboxylate group through the uncoordinated oxygen atom (O2), which does not allow the carboxylate group to bend to a greater extent. The dihedral angle between the aromatic ring (C2-C3-C4-C5-C6-C7) carrying the substituent and the plane defined by (O1-C1-O2) is 10° in **(1)**. On the contrary, the dihedral angle observed in **4** is 44.25 between the plane defined by (C7-C8-C9-C10-C11-C12) and (O1-C6-O2) shown in [Figure 8](#). This variation could be one of the factors in disrupting the isostructurality between the two isomorphous compounds.

**Figure 8** View along the carboxylate anion in **3** and **4** highlighting the orientation of the substituents (left) and dihedral angle between the mean plane through the benzene ring (C2-C3-C4-C5-C6-C7) and (O2-C1-O1) (**3**) and (C7-C8-C9-C10-C11-C12) and (O2-C6-O1) (**4**) (right)

Additionally, we conducted Hirshfeld surface analysis on the two isomorphous compounds to gain insights into the supramolecular non-covalent interactions. The HS for **3** and **4** is mapped over the  $d_{norm}$  range (-0.1753 to 1.7791) and (-0.2183 to 1.3441), respectively. The  $d_{norm}$  surfaces are indicative of short contacts such as N-H...C formed between the cyclam ligand and the carbon

1  
2  
3  
4 298 atom of the carboxylate ligand of neighboring molecule seen as a bright red area in the Hirshfeld  
5 surfaces (Figure 9 a). In the case of 4, short contacts C-H...O are observed between the carbon  
6 299 surfaces (Figure 9 a). In the case of 4, short contacts C-H...O are observed between the carbon  
7 atoms of the coordinated carboxylate (Figure 9 b), the oxygen atoms of the nitro group, and the  
8 300 uncoordinated oxygen atom of the carboxylate group. Comparatively, more O...H/H...O type  
9 301 interactions are witnessed in 4 with 32.2 % than in 3, as depicted in the 2D figure print plot of 3 (c  
10 302 and d) and 4 in (e and f). The difference in the interaction between the adjacent molecules indicates  
11 different packing of the molecules in the crystal lattice, resulting in disruption in isostructurality.  
12  
13  
14  
15  
16  
17

305  
306 **Figure 9** Intermolecular N-H...C interactions in 3 (a) and C-H...O in 4 (b). 2D Fingerprint  
307 showing full and O...H/H...O type interactions with the percentage of contribution to the total  
308 Hirshfeld surface area in 3 and 4.

309  
310 Compounds 5-8 were synthesized using benzoic acid as the parent acid and other substituted  
311 benzoic acids with chloro, methyl(thio), and amino group at the ortho position. The crystal  
312 structure analysis revealed that, except for 8, others showed isomorphism with similar unit cell  
313 parameters. Compounds 5-7 crystallize in a monoclinic crystal system with the  $P2_1/n$  space group,  
314 while 8 crystallize in the  $C2/c$  space group. All these compounds 5-8 have zinc ions placed in a  
315 special position. The asymmetric unit of compound 5 contains a Zn(II) ion coordinated to the  
316 cyclam ligand on the equatorial positions via the nitrogen atoms (N1, N2, N1i, and N2i) where  $i=$

1  
2  
3  
4 317  $-x, -y, -z$ . In contrast, the axial positions are occupied by the oxygen atoms from the coordinated  
5  
6 318 aqua molecules, forming a  $[\text{ZnN}_4\text{O}_2]$  coordination environment. The bond length of the metal to  
7  
8 319 nitrogen of the cyclam  $\text{Zn1-N1} = 2.1047(10) \text{ \AA}$ , slightly shorter than the metal to the oxygen atom  
9  
10 320 of the coordinated aqua ligand  $\text{Zn-O}$  bond distance is  $2.2453(10) \text{ \AA}$ . Similar observations are made  
11  
12 321 for compounds **6**, **7**, and **8**. The selected bond angles and bond distances are summarized in **Table**  
13  
14 322 **S2**. These bond distances and angles are consistent with the similarly reported compound having  
15  
16 323  $[\text{Zn}(\text{cyclam})]^{2+}$  cationic core<sup>27-30</sup>. This cationic unit then interacts with the uncoordinated  
17  
18 324 carboxylate anions through intramolecular hydrogen bonds, arising from the O-H of the aqua  
19  
20 325 molecules with the uncoordinated oxygen atom of the carboxylate group acting as the hydrogen  
21  
22 326 bond acceptor atoms and resulting in the formation of a zero-dimensional mononuclear compound.  
23  
24 327 Compound **7** differs slightly from their isomorphous group (**5** and **6**). It contains four aqua  
25  
26 328 molecules in its crystal lattice, which results in additional hydrogen bonding. The crystal structure  
27  
28 329 of compounds **5** and **7** are shown in **Figure 10**, while the figures for compounds **6** and **8** are in the  
29  
30 330 supplementary information (**Figure S5**).

2  
3  
4 351 supramolecular chain structure along the **b** axes (**Figure 11 b**). The non-ligated ligand aids in  
5  
6 352 interlinking the individual chain structure by forming a four-membered water cluster, which  
7  
8 353 extends along the ac plane, thereby rendering a 2D layered supramolecular network in compound  
9  
10 354 **7**, as depicted in the supplementary information (**Figure S6**). These structural changes indicate  
11  
12 355 little or no isostructurality between **5**, **6**, and **7**.

13  
14 356 A view of the supramolecular assembly of compound **8** is exhibited in **Figure 12**, The crystal  
15  
16 357 packing here is stabilized mainly by N-H $\cdots$ O and O-H $\cdots$ O type of interactions (**Table 3**) with  
17  
18 358 H $\cdots$ O distance in the range of 2.041 to 2.611 Å. compound **8** exhibits two intra- and four  
19  
20 359 intermolecular hydrogen bonding interactions responsible for stabilizing the crystal structure. The  
21  
22 360 amino group, unlike other substituents, participates in hydrogen bonding with the unbounded  
23  
24 361 carboxylate oxygen (O2), resulting in the formation of a chain-like structure, interlinking the  
25  
26 362 cationic units, thus resulting in the formation of a 1D ladder-shaped supramolecular layer.

373 It is evident that compounds **5-7** lack isostructurality due to significant variations in the hydrogen  
374 bonding situation in the crystal structure upon including different substituents. The cell similarity  
375 index  $\pi$  value for the molecular pair **5/6** is 0.0197, whereas, for **5/7**, it increases up to 0.2452. The  
376 highest deviation of the cell similarity index from zero is seen in the case of a **5/7** pair. It is  
377 attributed to the intense hydrogen bonding situation in compound **7**, which comprises non-ligated  
378 water molecules.

379 The Hirshfeld surface is mapped over  $d_{norm}$  range (-0.7068 to 1.4553) in **5**, (-0.72 to 1.3264) in **6**  
380 and (-0.6574 to 1.6115) in **7**. The red spots on the surface indicate the dominant interactions. The  
381 HS analysis indicates strong hydrogen bond interactions such as O-H $\cdots$ O and N-H $\cdots$ O co-exist  
382 between the cationic and the anionic unit in **5-7** shown in (**Figure 13 a-c**), respectively. The 2D  
383 fingerprint plots **5-7** shown in the supplementary information (**Figure S7**) exhibit the crucial  
384 contributors to crystal packing; the results are also expressed as a pie chart in **Figure 13 d-f** for  
385 compounds **5-7**. The majority of the contribution in all isomorphous compounds arises from the  
386 H $\cdots$ H type in the order of **5** > **7** > **6**. Compared to the parent compound (**5**), **6** and **7** exhibits H $\cdots$ Cl  
387 with 13.4 % contribution and H $\cdots$ S type with 6.7 % contribution in the respective compounds.  
388 Consequently, the additional interactions seen in **6** and **7** alter the crystal packing, thereby  
389 preventing the attainment of isostructurality.

**Figure 13** Intermolecular O-H $\cdots$ O and N-H $\cdots$ O type non-covalent interactions in **5** (a), **6**(b) and **7**(c).

## 2. 4. X-ray Powder diffraction

We then recorded their powder X-ray diffraction patterns to investigate the phase purity of the bulk material. The simulated data for all the compounds were obtained from the Mercury 4.0 software. The diffractograms for compounds **1** and **2** are shown in **Figure 14**, whereas for compounds **3/4** and **5-8**, the powder patterns are given in **Figures S8** and **S9**, respectively. The diffraction peaks in the stimulated pattern exactly matched the experimental data collected at room temperature, suggesting that the single crystal model represents the bulk crystalline material. Powder diffractograms can be a suitable technique for identifying isostructurality in related compounds as they show unique fingerprints of the solid compounds. Upon comparing the powder patterns of the related compounds, such as **1** with **2**, **3** with **4**, and **5-7**, it was observed that the powder patterns slightly varied, again suggesting that the related compounds sharing similar unit cell parameters are not isostructural.

**Figure 14** The XRD powder patterns of **1** and **2**

### 3. Conclusion

Eight zinc compounds (**1-8**) were synthesized and characterized using analytical techniques. The structural analysis of these compounds led to the exploration of rich solid-state chemistry, specifically dealing with the interaction of the carboxylate ligand with the zinc cyclam unit. The structural variation was achieved by switching the substituents at the *ortho* position relative to the carboxylate group on the aromatic ring. Introducing the methyl and methoxy substituents (**1**) and (**2**), respectively, resulted in a one-dimensional coordination polymer. In the structure, aqua molecules bridged the zinc ions of the cationic and the anionic units. The thermal profile of **1** was compared with **5**; it was observed that in **1**, the dehydration step appeared at a much higher temperature range than the dehydration in compound **5**, this is attributed to the different modes of coordination adopted by the aqua molecules in **1** and **5**. Compounds **1** and **2** further shared similar unit cell parameters with cell similarity index values close to zero; thus, the ISOS software identified the two compounds as isostructural. However, a lower isostructurality index and larger deviation in the  $D_{max}$  value obtained by overlaying the asymmetric units of **1** and **2** in mercury software suggested that the related compounds, although they share similar unit cell parameters, were not isostructural. The loss in isostructurality is attributed to the preference of the non-covalent interactions and orientation of the substituents relative to the coordinating carboxylate group in the

1  
2  
3  
4 425 respective compounds. These non-covalent interactions are theoretically predicted by Hirshfeld  
5  
6 426 surface analysis. Similarly, compound **3** was isomorphous to **4**; here, the carboxylate ligand  
7  
8 427 coordinated directly with the zinc ions, rendering a zero-dimensional compound. In **5-8**, the  
9  
10 428 carboxylate ligands did not coordinate with the zinc ion. They were held by the intramolecular  
11  
12 429 hydrogen bonds in the crystal lattice, with compound **7** also exhibiting additional aqua molecules  
13  
14 430 in the crystal lattice. The compounds **5-7** showed isomorphism, with significant variation in the  
15  
16 431 packing arrangement because of the chloro and (methylthio) substituents in the lattice compared  
17  
18 432 to the parent benzoate ligand. The addition of these substituents breaks the isostructurality as they  
19  
20 433 introduce the additional Cl...H/ H...Cl and S...H/ H...S type of non-covalent interactions as  
21  
22 434 identified theoretically by Hirshfeld surface analysis.
